

## Pseudo code

- We used `./input_functions` to import another file in our code.
- We defined a function name `read_name` which takes the use name and return the title and the name.
- Then, we define `read_address` so that we can read user address(unit number,street name,suburb, postcode) using `input_functions`.
- Then there's a `read_label` function which calls the `read_name` and `read_address` functions and return the name and address
- Here's a `read_message` function which reads message's subject and content
- Define `print_label_message` to take the label and message as arguments and prints thm
- Then we define a main function that calls `read_label` and `read_meassage`
- Then we call `main()` function to execute the program.
